Release 0.3.0

Michael V. DePalatis

December 08, 2015

1	Installation	3
2	Usage	5
3	Contributing	7
4	See also	9
5	License	11
6	Contents	13
6.1	Data storage and publishing	13
6.2	Request handlers	14
6.3	Changelog	15

An implementation of the publish/subscribe pattern for the [Tornado](#) web server.

Installation

Tornadose is on PyPI:

```
$ pip install tornadose
```

This will grab the latest official release. Alternatively, or for development, you can clone the repository and install it manually:

```
$ git clone https://github.com/mivade/tornadose.git
$ cd tornadose
$ python setup.py install
```

Usage

A simple example of using server-sent events (a.k.a. EventSource):

```
import random
from tornado.ioloop import IOLoop, PeriodicCallback
from tornado.web import Application
from tornadose.handlers import EventSource
from tornadose.stores import DataStore

store = DataStore()

app = Application(
    [(r'/', EventSource, {'store': store})],
    debug=True)
app.listen(9000)

loop = IOLoop.instance()
PeriodicCallback(lambda: store.set_data(random.random()), 1000).start()
loop.start()
```

To monitor the stream with `curl`:

```
$ curl http://localhost:9000
```

or with `HTTPIe`:

```
$ http -S get localhost:9000
```

Additional demos can be found in the `demos` directory.

Contributing

Contributions, complaints, criticisms, and whatever else are welcome. The source code and issue tracker can be found on [GitHub](#).

Tornadose is freely available under the terms of the MIT license. See `LICENSE` for details.

Contents

6.1 Data storage and publishing

In order to publish data to listeners, Tornadoose utilizes a data store concept somewhat reminiscent of that used in [Flux](#). In short, subscribers start listening to a data store and are notified when there are updates.

class `tornadoose.stores.BaseStore (*args, **kwargs)`

Base class for all data store types.

At a minimum, derived classes should implement `submit` and `publish` methods.

deregister (*subscriber*)

Stop publishing to a subscriber.

initialize (**args, **kwargs*)

Hook for doing custom initialization. Child classes should implement this method instead of overwriting `__init__`.

publish ()

Push messages to all listeners. This method must be implemented by child classes. A recommended way to implement this method is as a looping coroutine which yields until new data is available via the `submit ()` method.

register (*subscriber*)

Register a new subscriber. This method should be invoked by listeners to start receiving messages.

submit (*message*)

Add a new message to be pushed to subscribers. This method must be implemented by child classes.

This method exists to store new data. To actually publish the data, implement the `publish` method.

class `tornadoose.stores.DataStore (*args, **kwargs)`

Generic object for producing data to feed to clients.

To use this, simply instantiate and update the `data` property whenever new data is available. When creating a new `EventSource` handler, specify the `DataStore` instance so that the `EventSource` can listen for updates.

class `tornadoose.stores.QueueStore (*args, **kwargs)`

Publish data via queues.

This class is meant to be used in cases where subscribers should not miss any data. Compared to the `DataStore` class, new messages to be broadcast to clients are put in a queue to be processed in order.

`QueueStore` will work with any `tornado.web.RequestHandler` subclasses which implement a `submit` method. It is recommended that a custom subscription handler's `submit ()` method also utilize a

queue to avoid losing data. The subscriber must also register/deregister itself with the `QueueStore` via the `QueueStore.register()` and `QueueStore.deregister()` methods.

A `QueueStore`-compatible request handler is included in `tornado.handlers.WebSocketSubscriber`.

6.2 Request handlers

Tornado defines handlers for using the `EventSource` interface or `WebSockets`. For other handlers, the `BaseHandler` class is provided.

class `tornado.handlers.BaseHandler` (*application, request, **kwargs*)

Bases: `tornado.web.RequestHandler`

Base handler for subscribers. To be compatible with data stores defined in `tornado.stores`, custom handlers should inherit this class and implement the `submit()` and `publish()` methods.

initialize (*store*)

Common initialization of handlers happens here. If additional initialization is required, this method must either be called with `super` or the child class must assign the `store` attribute and register itself with the store.

publish ()

Push a message to the subscriber. This method must be implemented by child classes.

submit (**args, **kwargs*)

Submit a new message to be published.

class `tornado.handlers.EventSource` (*application, request, **kwargs*)

Bases: `tornado.handlers.BaseHandler`

Handler for server-sent events a.k.a. EventSource.

The `EventSource` interface has a few advantages over websockets:

- It is a normal HTTP connection and so can be more easily monitored than websockets using tools like `curl` or `HTTPIe`.
- Browsers generally automatically try to reestablish a lost connection.
- The publish/subscribe pattern is better suited to some applications than the full duplex model of websockets.

publish (**args, **kwargs*)

Pushes data to a listener.

class `tornado.handlers.WebSocketSubscriber` (*application, request, **kwargs*)

Bases: `tornado.handlers.BaseHandler`, `tornado.websocket.WebSocketHandler`

A WebSocket-based subscription handler.

open (**args, **kwargs*)

Register with the publisher.

publish (**args, **kwargs*)

Push a new message to the client. The data will be available as a JSON object with the key `data`.

6.3 Changelog

6.3.1 Version 0.3.0

2015-12-08

- Improve performance by always using a Queue for message handling.

6.3.2 Version 0.2.2

2015-10-21

- Fix bug that printed out all messages sent with websocket subscribers which was originally present for debugging purposes.

6.3.3 Version 0.2.1

2015-10-17

- Subscription handlers automatically get registered with stores. This simplifies creating custom handlers.

6.3.4 Version 0.2.0

2015-10-11

- Reworks stores and handlers (backwards incompatible!).
- Adds a new queue-based `QueueStore` store.
- Implements a websocket-based subscriber to supplement `EventSource`.
- Begins to add unit testing.

6.3.5 Version 0.1.2

2015-09-20

- Defines an `EventSource` request handler and a `DataStore` object for using server-sent events with Tornado.

B

BaseHandler (class in `tornadose.handlers`), [14](#)

BaseStore (class in `tornadose.stores`), [13](#)

D

DataStore (class in `tornadose.stores`), [13](#)

deregister() (`tornadose.stores.BaseStore` method), [13](#)

E

EventSource (class in `tornadose.handlers`), [14](#)

I

initialize() (`tornadose.handlers.BaseHandler` method), [14](#)

initialize() (`tornadose.stores.BaseStore` method), [13](#)

O

open() (`tornadose.handlers.WebSocketSubscriber` method), [14](#)

P

publish() (`tornadose.handlers.BaseHandler` method), [14](#)

publish() (`tornadose.handlers.EventSource` method), [14](#)

publish() (`tornadose.handlers.WebSocketSubscriber` method), [14](#)

publish() (`tornadose.stores.BaseStore` method), [13](#)

Q

QueueStore (class in `tornadose.stores`), [13](#)

R

register() (`tornadose.stores.BaseStore` method), [13](#)

S

submit() (`tornadose.handlers.BaseHandler` method), [14](#)

submit() (`tornadose.stores.BaseStore` method), [13](#)

W

WebSocketSubscriber (class in `tornadose.handlers`), [14](#)
